**METHOD FOR THE PREPARATION
OF METALLOCENE CATALYSTS**

FIELD OF THE INVENTION

This invention relates to supported metallocene catalyst systems useful in the polymerization of ethylenically unsaturated compounds and, more particularly, to processes for the preparation of supported metallocene catalysts.

BACKGROUND OF THE INVENTION

Numerous catalyst systems for use in the polymerization of ethylenically unsaturated monomers are based upon metallocenes. Metallocenes can be characterized generally as coordination compounds incorporating one or more cyclopentadienyl(Cp) groups (which may be 5 substituted or unsubstituted) coordinated with a transition metal through π bonding. When certain metallocene compounds are combined with an activator or cocatalyst such as methylaluminoxane (MAO) and optionally an alkylation/scavenging agent such as trialkylaluminum compound, highly active polymerization catalysts are formed. Various types of metallocenes are known in the art. As disclosed, for example, in U.S. Patent No. 5,324,800 to Welborn et al, they include monocyclic (a single cyclopentadienyl group), bicyclic (two cyclopentadienyl groups, as shown in Formula 10 1), or tricyclic (three cyclopentadienyl groups) coordinated with a central transition metal. Homogeneous or non-supported metallocene catalysts are known for their high catalytic activity especially in olefin polymerizations. Under polymerization conditions where polymer is formed as solid particles, these homogeneous (soluble) catalysts form deposits of polymer on reactor 15 walls and stirrers, which deposits should be removed frequently as they prevent an efficient heat-exchange, necessary for cooling the reactor contents, and cause excessive wear of the moving parts. In addition, solid particles formed by such homogeneous catalysts possess undesirable particle morphologies with low bulk densities which make them difficult to circulate in the reactor, limiting throughput and they are difficult to convey outside of the reactor. In order to 20 resolve these difficulties several supported metallocene compounds have been proposed. As disclosed in Welborn et al, typical supports include inorganic materials such as silica, alumina, or polymeric materials such as polyethylene.

Metallocene compounds, whether supported or unsupported, can further be characterized in terms of stereoregular catalysts which result in polymerization of alpha olefins, such as propylene, to produce crystalline stereoregular polymers, the most common of which are isotactic polypropylene and syndiotactic polypropylene. In general, stereospecific metallocene catalysts possess at least one chiral center and the ligand structure (usually cyclopentadienyl-based) are conformationally restricted. Due to the fluxional nature of Cp-type ligands, it is common for at least one of the Cp ligands to be suitably substituted to impart some measure of stereorigidity. Such stereospecific metallocenes can include unbridged bicyclic compounds of the general formula bicyclic coordination compounds of the general formula:

which are characterized by the isospecific metallocenes as described below and dicyclopentadienyl compounds of the general formula:

characterized by the syndiospecific metallocenes described below. In the aforementioned formulas, Me denotes a transition metal element and Cp and Cp' each denote a cyclopentadienyl group which can be either substituted or unsubstituted with Cp' being different from Cp, Q is an alkyl or other 20 hydrocarbyl or a halogen group (most typically a 2 electron donor group) and n is a number within the range of 1-3. In such instances stereorigidity can be provided through substituent groups which result in steric hindrance between the two cyclopentadienyl moieties as described, for example, in U.S. Patent No. 5,243,002 to Razavi. Alternatively, the cyclopentadienyl groups are in a

conformationally restricted relationship provided by a bridged structure between the metallocene rings (not shown in Formulas (1) and (2) above). It is sometimes advantageous to utilize metallocene compounds in which the two cyclopentadienyl moieties (same or different) are covalently linked by a so-called bridging group such as a dimethylsilylene group. The bridging group restricts rotation of the two cyclopentadienyl moieties and in many instances improves catalyst performance. Metallocenes containing such a bridging group are often referred to as stereorigid.

While bridged metallocenes normally incorporate two cyclopentadienyl groups (or substituted cyclopentadienyl groups), bridged metallocenes incorporating a single cyclopentadienyl group which is bridged to a heteroatom aromatic group (both being coordinated with a transition metal) are also known in the art. For example, U.S. Patent No. 5,026,798 to Canich discloses dimethylsilyl-bridged cyclopentadienyl -- anilino or other heteroatom ligand structures with coordination to the transition metal being provided through the nitrogen atom of the anilino group as well as the cyclopentadienyl-group. Other common bridging groups include CR_1R_2 , $CR_1R_2CR_2R_3$, SiR_1R_2 , and $SiR_1R_2SiR_1R_2$ where the R_i substituents can be independently selected from H or a C_1-C_{20} hydrocarbyl radical. Alternate bridging groups can also contain nitrogen, phosphorus, boron or aluminum.

As noted previously, isospecific and syndiospecific metallocene catalysts are useful in the stereospecific polymerization of monomers. Stereospecific structural relationships of 20 syndiotacticity and isotacticity may be involved in the formation of stereoregular polymers from various monomers. Stereospecific propagation may be applied in the polymerization of ethylenically unsaturated monomers such as C_3 to C_{20} alpha olefins which can be linear, branched,

or cyclic, 1-dienes such as 1,3-butadiene, substituted vinyl compounds such as vinyl aromatics, *e.g.*, styrene or vinyl chloride, vinyl chloride, vinyl ethers such as alkyl vinyl ethers, *e.g.*, isobutyl vinyl ether, or even aryl vinyl ethers. Stereospecific polymer propagation is probably of most significance in the production of polypropylene of isotactic or syndiotactic structure.

5 The structure of isotactic polypropylene can be described as one having the methyl groups attached to the tertiary carbon atoms of successive monomeric units falling on the same side of a hypothetical plane through the main chain of the polymer, *e.g.*, the methyl groups are all above or below the plane. Using the Fischer projection formula, the stereochemical sequence of isotactic polypropylene can be described as follows:

15 In Formula 3 each vertical segment indicates a methyl group on the same side of the polymer backbone. In the case of isotactic polypropylene the majority of inserted propylene units possess the same relative configuration in relation to its neighboring propylene unit. Another way of describing the structure is through the use of NMR. Bovey's NMR nomenclature for an isotactic sequence as shown above is ...mmmm... with each "m" representing a "meso" dyad in which there is a mirror plane of symmetry between two adjacent monomer units, or successive pairs of methyl groups on the same side of the plane of the polymer chain. As is known in the art, any deviation or 20 inversion in the structure of the chain lowers the degree of isotacticity and subsequently the crystallinity of the polymer.

In contrast to the isotactic structure, syndiotactic propylene polymers are those in which the methyl groups attached to the tertiary carbon atoms of successive monomeric units in the chain lie

on alternate sides of the plane of the polymer. In the case of syndiotactic polypropylene, the majority of inserted propylene units have opposite relative configuration relative to its neighboring monomer unit. Syndiotactic polypropylene in using the Fisher projection formula can be indicated by racemic dyads with the syndiotactic sequence ...rrrr... shown as follows:

5

Bovey's NMR nomenclature for a syndiotactic sequence as shown above is ...rrrr... with each "r" representing a "racemic" dyad in which successive pairs of methyl groups are on the opposite sides of the plane of the polymer chain. Similarly, any deviation or inversion in the structure of the chain lowers the degree of syndiotacticity and subsequently the crystallinity of the polymer.

The vertical segments in the preceding example indicate methyl groups in the case of syndiotactic or isotactic polypropylene. Other terminal groups, *e.g.* ethyl, in the case of poly-1-butene, chloride, in the case of polyvinyl chloride, or phenyl groups in the case of polystyrene and so on can be equally described in this fashion as either isotactic or syndiotactic.

Polypropylene resins can also be obtained in which the propylene units are inserted in a more or less random configuration. Such materials are referred to as atactic and as such, these polymers lack any signs of crystallinity as determined by common methods of X-ray diffraction, heat of fusion by Differential Scanning Calorimetry, or density. Such atactic polymers also tend to 20 be more soluble in hydrocarbon solvents than polymers which possess some crystallinity. Syndiotactic polymers with sufficiently high levels of syndiotacticity and isotactic polymers with sufficiently high levels of isotacticity are semi-crystalline. Similarly this can be established by any technique known to those skilled in the art such as XRD, DSC, or density measurements. It is

5

common for polymers to be obtained as a mixture of highly stereoregular polymer and atactic polymer. In such instances, it is often useful to perform solubility testing, such as the mass fraction soluble in xylene or boiling heptane for instance to establish the amount of atactic polymer present. In most instances, atactic polymers are more soluble than the stereoregular counterparts and therefore the mass fraction soluble in hydrocarbons provides an indirect indication of the amount of atactic polymer present. While various other stereoregular or quasi-stereoregular polymer structures, such as hemiisotactic or stereoisoblock structures, are known, the principal stereoregular polymer configurations of interest are predominantly isotactic and predominantly syndiotactic polymers.

Catalysts that produce isotactic polyolefins are disclosed in U.S. Patent Nos. 4,794,096 and 4,975,403. These patents disclose chiral, stereorigid metallocene catalysts that polymerize olefins to form isotactic polymers and are especially useful in the polymerization of highly isotactic polypropylene. As disclosed, for example, in the aforementioned U.S. Patent No. 4,794,096, stereorigidity in a metallocene ligand is imparted by means of a structural bridge extending between cyclopentadienyl groups. Specifically disclosed in this patent are stereoregular hafnium metallocenes which may be characterized by the following formula:

In Formula (5), $(C_5(R')_4)$ is a cyclopentadienyl or substituted cyclopentadienyl group, R' is independently hydrogen or a hydrocarbyl radical having 1-20 carbon atoms, and R'' is a structural bridge extending between the cyclopentadienyl rings. Q is a halogen or a hydrocarbon radical, such as an alkyl, aryl, alkenyl, alkylaryl, or arylalkyl, having 1-20 carbon atoms and p is 2.

Catalysts that produce syndiotactic polypropylene or other syndiotactic polyolefins and methods for the preparation of such catalysts are disclosed in U.S. Patent Nos. 4,892, 851 to Ewen et al and 5,807,800 to Shamshoum et al. These catalysts are also bridged stereorigid metallocene catalysts, but, in this case, the catalysts have a structural bridge extending between chemically dissimilar cyclopentadienyl groups and may be characterized by the formula:

In Formula (6), Cp represents a cyclopentadienyl or substituted cyclopentadienyl ring, and R and R' represent hydrocarbyl radicals having 1-20 carbon atoms. R'' is a structural bridge between the rings imparting stereorigidity to the catalyst. Me represents a transition metal, and Q a hydrocarbyl radical or halogen. R'_m is selected so that (CpR'_m) is a sterically different substituted cyclopentadienyl ring than (CpR_n). In Formula (6) n varies from 0-4 (0 designating no hydrocarbyl groups, *i.e.*, no further substitution other than the bridging substituent on the cyclopentadienyl ring), m varies from 1-4, and k is from 0-3. The sterically different cyclopentadienyl rings produce a predominantly syndiotactic polymer rather than an isotactic polymer.

Like their isospecific counterparts, the syndiospecific metallocenes are used in combination with co-catalysts. One particularly useful class of co-catalysts are based on organoaluminum compounds which may take the form of an alumoxane, such as 20 methylalumoxane or a modified alkylaluminoxane compound. Alumoxane (also referred to as aluminoxane) is an oligomeric or polymeric aluminum oxy compound containing chains of alternating aluminum and oxygen atoms, whereby the aluminum carries a substituent preferably an alkyl group. The exact structure of aluminoxane is not known, but is generally believed to be

represented by the following general formula $-(Al(R)-O-)_m$, for a cyclic alumoxane, and $R_2Al-O-(Al(R)-O)_m-AlR_2$ for a linear compound, wherein R independently each occurrence is a C_1-C_{10} hydrocarbyl, preferably alkyl, or halide and m is an integer ranging from 1 to about 50, preferably at least about 4. Alumoxanes are typically the reaction products of water and an aluminum alkyl, which in addition to an alkyl group may contain halide or alkoxide groups.

5 Reacting several different aluminum alkyl compounds, such as, for example, trimethylaluminum and tri-isobutyl aluminum, with water yields so-called modified or mixed alumoxanes. Preferred alumoxanes are methylalumoxane and methylalumoxane modified with minor amounts of other lower alkyl groups such as isobutyl. Alumoxanes generally contain minor to substantial amounts of starting aluminum alkyl compound(s). Other cocatalysts include trialkylaluminum, such as triethylaluminum (TEAl) or triisobutylaluminum (TIBAL) or mixtures thereof. Specifically disclosed in the '851 patent is methylalumoxane and triethylaluminum (TEAl).

10 Bridged metallocene ligands having a dissimilar cyclopentadienyl groups can result from the reaction of 6, 6-dimethyl fulvene with a substituted cyclopentadiene such as fluorene or substituted fluorene derivative, to produce a ligand characterized by an isopropylidene bridge structure. Preferably, this ligand structure is characterized as having bilateral symmetry such as indicated by the isopropylidene(cyclopentadienyl fluorenyl) structure as shown in Formula 9 of the aforementioned Patent No. 5,807,800. As described in the Shamshoum et al '800 patent, the bilateral symmetry of the ligand structure is indicated by the balanced orientation about the broken 15 line representing a plane of symmetry extending generally through the bridge structure and the transition metal atom.

As disclosed in the aforementioned Patent No. 5,324,800 to Welborn, supported catalysts can be prepared by converting a soluble metallocene to a heterogenous catalyst by depositing the metallocene on a suitable catalyst support. Other supported catalysts are disclosed in U.S. Patent Nos. 4,701,432 and 4,808,561, both to Welborn, U.S. Patent No. 5,308,811 to Suga et al, Patent No. 5,444,134 to Matsumoto, Patent No. 5,719,241 to Razavi and the aforementioned Patent No. 5,807,800 to Shamshoum et al.

As described in the Welborn '432 patent, the support may be any support such as talc, an inorganic oxide, or a resinous support material such as a polyolefin. Specific inorganic oxides include silica and alumina, used alone or in combination with other inorganic oxides such as magnesia, titania, zirconia, and the like. Non-metallocene transition metal compounds, such as titanium tetrachloride, are also incorporated into the supported catalyst component. The inorganic oxides used as support are characterized as having an average particle size ranging from 30-600 microns, preferably 30-100 microns, a surface area of 50-1,000 square meters per gram, preferably 100-400 square meters per gram, a pore volume of 0.5-3.5 cc/g, preferably about 0.5-2 cc/g. Generally, the particle size, surface area, pore volume, and number of surface hydroxyl groups are said to be not critical to the Welborn procedure. Specifically disclosed in Welborn is a catalyst in which bis(cyclopentadienyl)zirconium dichloride (unbridged metallocene) is supported on a high surface area silica dehydrated in dry nitrogen at 600°C and characterized as Davison 952. The Welborn '561 patent discloses a heterogeneous catalyst which is formed by the reaction of a metallocene and an alumoxane in combination with the support material. The support in Welborn '561 is described similarly as the support in the Welborn '432 patent. Various other catalyst systems involving supported metallocene catalysts are disclosed in U.S. Patent Nos. 5,308,811 to Suga et al

and 5,444,134 to Matsumoto. In both patents the supports are characterized as various high surface area inorganic oxides or clay-like materials. In the patent to Suga et al, the support materials are characterized as clay minerals, ion-exchanged layered compounds, diatomaceous earth, silicates, or zeolites. As explained in Suga, the high surface area support materials should have volumes of 5 pores having radii of at least 20 Angstroms. Specifically disclosed and preferred in Suga are clay and clay minerals such as montmorillonite. The catalyst components in Suga are prepared by mixing the support material, the metallocene, and an organoaluminum compound such as triethylaluminum, trimethylaluminum, various alkylaluminum chlorides, alkoxides, or hydrides or an alumoxane such as methylalumoxane, ethylalumoxane, or the like. The three components may 10 be mixed together in any order, or they may be simultaneously contacted. The patent to Matsumoto similarly discloses a supported catalyst in which the support may be provided by inorganic oxide carriers such as SiO_2 , Al_2O_3 , MgO , ZrO_2 , TiO_2 , Fe_2O_3 , B_2O_2 , CaO , ZnO , BaO , ThO_2 and mixtures 15 thereof, such as silica alumina, zeolite, ferrite, and glass fibers. Other carriers include MgCl_2 , $\text{Mg}(\text{O-Et})_2$, and polymers such as polystyrene, polyethylene, polypropylene, substituted polystyrene and polyarylate, starches, and carbon. The carrier has a surface area of 1-1000 m^2/g , preferably 50-500 m^2/g , a pore volume of 0.1-5 cm^3/g , preferably 0.3-3 cm^3/g , and a particle size of 20-100 microns.

Of the various inorganic oxides used as supports, silica, in one form or another, is widely 20 disclosed as a support material for metallocene catalysts. The aforementioned Patent No. 5,719,241 to Razavi, while disclosing a wide range of inorganic oxides and resinous support materials, identifies the preferred support as a silica having a surface area between about 200 and 600 m^2/g and a pore volume between 0.5 and 3 ml/g . Specifically disclosed is a support

5

identified as Grace '952 having a surface area of 322 m²/g. In preparing the supported metallocenes as described in Razavi, the silica is dried under a vacuum for three hours to remove water and then suspended in toluene where it is reacted with methylalumoxane for three hours at reflux temperature. The silica is washed three times with toluene to remove the unreacted alumoxane after which a solution of two metallocenes is added and the mixture stirred for an hour. The supernatant liquid is then withdrawn, and the solid support containing the metallocene is washed with toluene and then dried under vacuum. Silica characterized as Davison D-948 or Davison D-952 also appears as a conventional metallocene support. For example, U.S. Patent No. 5,466,649 to Jejelowo discloses the use of dehydrated Davison D-948 silica as a support for various unbridged metallocenes used in conjunction with supported co-catalysts. Patent No. 5,498,581 to Welch et al discloses silica for use as a support for either bridged or unbridged metallocenes in which the silica is treated with carbon monoxide, water, and hydroxyl groups. Specifically disclosed is the silica, Davison D-948, having an average particle size of 50 microns. Other silica-based supports are disclosed in U.S. Patent Nos. 5,281,679 to Jejelowa, 5,238,892 to Chang, and 15 5,399,636 to Alt. The Chang and Jejelowa patents disclose the use of a silica support identified as Davison D-948, which is characterized as a amorphous silica gel containing about 9.7 wt.% water. As described in the Chang and Jejelowa patents, alumoxane is formed directly on the surface of the silica gel by direct reaction of an alkyl aluminum with silica gel which is undehydrated so as to ensure the conversion of the quantity of the alkyl aluminum to an alumoxane that has a high degree 20 of oligomerization. The water-impregnated gel is characterized as having a surface range of 10-700 m²/g, a pore volume of about 0.5-3 cc/g, and an absorbed water content of from about 10-50 wt.% in the case of the Jejelowa patent and about 6-20 wt.% in the case of the Chang patent. The average

particle size for the silica is described in Chang to be from 0.3-100 microns and in Jejelowa from about 10-100 microns. After the alumoxane silica gel component has been formed, the metallocene may be added to the wet slurry.

Other supported catalyst systems are disclosed in European Patent Application No. 5 96111719.9 (EPO 819706A1) to Shamshoum et al. Here a silica support such as described above is pretreated with an alumoxane, such as methylalumoxane followed by addition of a syndiospecific metallocene on the MAO-treated silica. The supported metallocene is used in conjunction with an organo-aluminum co-catalyst such as a monoalkyl or dialkyl aluminum halides as described previously, including trialkylaluminums such as trimethylaluminum, triethylaluminum or tri-isobutyl aluminum (TIBAL). In the supported catalyst disclosed in EPO819706, the silica support is a high surface area, small pore size silica which is first dried, slurried in a non-polar solvent, and then contacted with methylalumoxane in a solvent. The metallocene was then dissolved in a non-polar solvent, particularly the same as used as the solvent for the alumoxane. The solid metallocene supported on the alumoxane-treated silica is then recovered from the solvent, dried, and then incorporated into carrier liquid such as mineral oil. The Shamshoum EPA application also discloses a pre-polymerization step which can be used to decrease the aging time of the catalyst in the trialkyl aluminum or other aluminum co-catalyst.

Yet, other supported catalyst systems incorporating bridged metallocene catalysts are 20 disclosed in U.S. Patent No. 5,968,864 to Shamshoum et al. Here, catalyst efficiency is improved by preparation procedure in which a support such as silica is treated with alumoxane in a non-polar solvent such as toluene and contacted with a solution of a metallocene at a reduced

temperature, preferably in the range of 0°C to -20°C. The resulting solid is then washed with hexane and dried overnight at room temperature.

31223:71413 : DALLAS : 599313.4

SUMMARY OF THE INVENTION

In accordance with the present invention, there is provided a process for the preparation of a supported metallocene catalyst in which the metallocene and co-catalysts components can be tailored with respect to the support to provide a supported catalyst system which can be isolated and stored in a mineral oil slurry to be used in the production of stereoregular polymers while alleviating or eliminating problems associated with reactor fouling and undesirable polymer fines. The resulting supported catalyst provides good activity which can be maintained when the process is used to produce an isospecific or a syndiospecific supported catalyst.

In carrying out the invention, there is provided a particulate catalyst support material in which an alumoxane co-catalyst is incorporated onto the support particles. The support material is contacted with a dispersion of a metallocene catalyst in an aromatic hydrocarbon solvent. The metallocene solvent dispersion and the alumoxane-containing support are mixed at a temperature of about 10°C or less for a period sufficient to enable the metallocene to become reactively supported on the alumoxane-support material. Following the mixing time, which typically can vary from a few minutes to a number of hours, the supported catalyst is recovered from the aromatic solvent and then washed optionally with an aromatic hydrocarbon and then sequentially with a paraffinic hydrocarbon solvent in order to remove substantial quantities of aromatic solvent from the supported catalyst. These washing procedures are carried out at a low temperature of about 10°C or less. Thereafter, the washed catalyst is dispersed in a viscous mineral oil having a viscosity which is substantially greater than the viscosity of the paraffinic hydrocarbon solvent. Typically, the mineral oil has a viscosity at 40°C of at least 65 centistokes as measured by ASTM D445. This may be contrasted with the viscosity of the paraffinic

hydrocarbon solvent which usually will be no more than 2 and preferably no more than 1 centipoise at the reduced temperature conditions. Steps need not be taken to dry the washed catalyst, and typically the washed catalyst at the time of the dispersion will contain a substantial residual amount of the paraffinic hydrocarbon solvent and some quantity of aromatic 5 hydrocarbon solvent. Preferably, after the supported catalyst is recovered from the aromatic solvent and before washing with the paraffinic hydrocarbon solvent, a further washing step is carried out with an aromatic solvent to remove unsupported metallocene from the supported catalyst.

In a further aspect of the invention, there is provided a particulate catalyst support which 10 preferably is a particulate silica having a particle size within the range of 10-100 microns, and preferably, silica having a spheroidal configuration with an average particle size within the range of about 10-60 microns, and more preferably, 10-15 microns. Typically, the silica will be dried at an elevated temperature for a period of time to moderately dehydrate the silica. Often a mild heat treatment such as 100°C to 160°C is sufficient although higher temperatures can be 15 employed. The particulate support material is then contacted with an alumoxane co-catalyst in an aromatic carrier liquid. The mixture of support, carrier liquid, and alumoxane co-catalyst is heated at an elevated temperature for a period of time to fix the alumoxane on the particulate support. For example, the mixture may be heated under reflux conditions of about 100°C or 20 more for a period ranging from one hour to several hours. The mixture is then cooled and the alumoxane-containing support is separated from the carrier liquid. The alumoxane-containing support material is then washed with an aromatic hydrocarbon solvent in order to remove excess unsupported or free alumoxane (or aluminum alkyl residuals) so that substantially all of the

alumoxane is fixed to the support. The alumoxane-containing support material is then cooled to a reduced temperature of about 10°C or less, and a dispersion of metallocene in an aromatic solvent is added with mixing as described above at a temperature of about 10°C or less to allow the metallocene to become reactively supported on the alumoxane-containing support material.

5 The supported catalyst is then recovered, washed with a low viscosity paraffinic hydrocarbon solvent at a reduced temperature of about 10°C or less as described above and then dispersed in a viscous mineral oil. Alternatively, the catalyst is washed with mineral oil and no paraffinic hydrocarbon solvent is used. Polyolefin catalysts prepared in this fashion have superior performance qualities such as higher activity.

DETAILED DESCRIPTION OF THE INVENTION

The present invention involves processes for the preparation of supported metallocenes which are carried out generally under low temperature conditions for the deposition of metallocene catalysts on the alumoxane-containing support and in which the supported 5 metallocene, once obtained, is directly dispersed in a mineral oil carrier. Such supported catalysts are suitable for use in the polymerization of ethylene, propylene, and higher olefins including the homopolymerization of such olefins or the copolymerization thereof, such as in the preparation of ethylene/propylene copolymers. The procedure is in contrast to the prior art procedure, such as disclosed in the aforementioned patents to Welborn in which the metallocene and alumoxane are added generally at room temperature conditions, and regardless of the order of addition employed, the final catalyst particles are dried for prolonged periods of time in order to remove volatile materials. Similarly, in procedures such as disclosed in the aforementioned 10 Razavi '241 patent where alumoxane is added first and mixed with the support at reflux temperature, the final supported catalyst is dried under vacuum. In contrast with the prior art procedure, the present invention proceeds once the alumoxane is fixed on the support to carry out 15 the metallocene support reaction under low temperature conditions, typically within the range of about -20° to 10°C followed by washing the catalyst with hydrocarbons and directly dispersing the washed catalyst into a viscous mineral oil without an intervening drying step. The washes and dispersal of catalyst into the mineral oil is carried out under subambient temperature 20 conditions.

The supported catalyst produced in accordance with the present invention provides several important features. Metallocene loading and alumoxane loading on the support material

can be controlled to desired levels. This is particularly significant in the case of certain silica supports preferred for use in the present invention where it is desired to control alumoxane/silica ratios to levels which may vary depending upon the nature of the metallocene component. Particularly in the case of stereospecific metallocenes, the alumoxane/silica ratio is controlled to 5 arrive at desired ratios for effective characteristics of the final catalyst in terms of metallocene activation, polymer fines, fouling during the polymerization procedure, and imperfections sometimes referred to as "fish eyes" in finished products produced from the olefin polymer. Moreover, for metallocenes and support materials other than the preferred stereospecific metallocenes and silica supports, the invention still provides a process in which loading of the metallocene on an alumoxane containing support can be accomplished at relatively low temperatures and by direct dispersion of the supported catalyst into a viscous mineral oil dispersion without an intervening drying step as commonly practiced in the prior art techniques. The resulting catalyst systems have generally higher activities with very little decay in activity, *i.e.* long "shelf life," during storage prior to use especially when catalyst is stored cold.

15 The catalysts further are subject to activity enhancement by aging with an alkylaluminum compound, such as triisobutylaluminum (TIBAL) in accordance with an aging procedure as disclosed in U.S. Patent Application Serial No. 09/086,080, filed May 28, 1998, by Edwar Shamshoum et al, entitled "Process for the Syndiotactic Propagation of Olefins." Briefly, activity enhancement of the catalyst can be accomplished by aging the supported metallocene in 20 an organoaluminum compound, specifically TIBAL, in a mineral oil overnight (about 12 hours) or for further periods, *e.g.*, for one or two days, in accordance with the following procedure. A specific aging procedure involves contacting equal parts of the supported metallocene and equal

5 parts of the TIBAL in a mineral oil slurry and allowing them to stand at room temperature, 25°C for an overnight period (about 12 hours) prior to polymerization. A typical master batch of the syndiospecific catalyst or the isospecific catalyst can be prepared from a slurry of 180 mg. of the supported metallocene (the metallocene and the support), 8.3 ml. of mineral oil, and 180 mg. of TIBAL in a concentration of 25 wt.% in hexane. After the overnight aging procedure, a 1.0 ml. aliquot of the master slurry is used for each propylene polymerization. For further description of the aging process, reference is made to the aforementioned Application Serial No. 09/086,080, the entire disclosure of which is incorporated herein by reference.

10 As noted previously, the present invention provides a process for loading of a metallocene catalyst precursor on an alumoxane-containing support material with subsequent dispersion in a mineral oil carrier liquid as well as a preferred procedure for loading alumoxane on a support material which is particularly applicable to certain silica supports. However, the invention, while especially preferred for use employing the silica supports, can also be carried out with other support materials, such as disclosed, for example, in the aforementioned Patent No. 5,719,241 to Razavi, and which includes polyolefins, such as polyethylene or polypropylene, polystyrenes, and inorganic oxides other than silica, such as alumina, magnesia, titania, and other inorganic oxides. Talc, such as disclosed in Razavi, and clay and clay minerals, such as disclosed in the aforementioned patent to Suga et al, can also be used as support material. Zeolite and glass fibers can be used as well as other inorganic oxides, such Fe_2O_3 , B_2O_2 , CaO ,
20 ZnO , BaO , ThO_2 , $MgCO^2$, and $Mg(O-Et)_2$, disclosed in the aforementioned patent to Matsumoto, can be used also in the present invention, although they usually will be less desirable than the preferred silica supports. Support materials which can be used in carrying out the present

invention, are disclosed in the aforementioned Patent Nos. 5,719,241 to Razavi, 5,308,811 to Suga et al, and 5,444,134 to Matsumoto, the entire disclosures of which are incorporated herein by reference.

One suitable class of silica support employed in the present invention include silica particles having an average size within the range of about 10-100 microns, including silica particles which function to support the alumoxane on the outer surfaces thereof. Specifically included in such silica supports is a particulate silica having a spheroidal configuration and an average particle size within the range of about 10-60 microns. One such support is available from Asahi Glass Company, Ltd., under the designation of H-121. Such silica supports are spheroidal in nature and have an average particle size of about 12 microns and a pore volume of about 0.9 milliliters per gram. As described below, the alumoxane becomes fixed primarily on the outer surface of the spheroidal silica particles. The average particle size of the silica is enhanced substantially by a value of about 0.5 microns or more after addition of the alumoxane on the support using the protocol of the present invention in which the alumoxane, after incorporation on the support particle by refluxing in a solvent, is cooled and washed. Furthermore, it is common for the MAO / support to form aggregated species whose average particle size is substantially larger than the starting support.

The metallocenes employed in the present invention include metallocene compounds which are known as useful in olefin polymerization procedures and include monocyclic, bicyclic, 20 or tricyclic olefins as disclosed in the aforementioned Patent No. 5,324,800 to Welborn and Patent No. 5,719,241 to Razavi et al. However, the invention is particularly applicable to the preparation of supported metallocenes based upon stereospecific metallocenes, specifically

isospecific and syndiospecific metallocenes. As discussed below, different parameters in terms of alumoxane loading and metallocene content are applicable in forming isospecific and syndiospecific supported metallocenes, and the present invention readily accommodates close control of alumoxane and metallocene loading within relatively narrow ranges.

Stereorigid metallocenes, which are preferred for use in the present invention, can be characterized as metallocenes incorporating a ligand structure having at least one suitable substituent on at least one cyclopentadienyl ring coordinated with a central transition metal. At least one of the cyclopentadienyl rings is substituted and provides an orientation with respect to the transition metal which is sterically different from the orientation of the other cyclopentadienyl group. Thus, both of the cyclopentadienyl groups are in a relationship with one another providing a stereorigid relationship relative to the coordinating transition metal atom to substantially prevent rotation of the ring structures. The sterically dissimilar ring structures may be chemically identical as in the case of certain isospecific metallocenes or chemically different as in the case of syndiospecific metallocenes. However, if two chemically identical cyclopentadienyl groups are involved in the ligand structure, they must be sterically different, as in the case of racemic bis(indenyl) structures, rather sterically the same relative to the transition metal, as in the case of meso bis(indenyl) ligand structures.

Bridged isospecific metallocenes can be characterized as chiral stereorigid metallocenes defined by the following formula:

$$R''(C_p(R')_4)_2MeQ_p \quad (7)$$

wherein each $(C_p(R')_4)$ is a substituted cyclopentadienyl ring; each R' is the same or different and is a hydrogen or hydrocarbyl radical having 1-20 carbon atoms; R'' is a structural bridge between the

two $(C_p(R')_4$ rings imparting stereorigidity to said catalyst with the two $(C_p(R')_4$ rings being in a racemic configuration relative to Me, and R" is selected from the group consisting of a substituted or unsubstituted alkylene radical having 1-4 carbon atoms, a silicon hydrocarbyl radical, a germanium hydrocarbyl radical, a phosphorus hydrocarbyl radical, a nitrogen hydrocarbyl radical, a 5 boron hydrocarbyl radical, and an aluminum hydrocarbyl radical; Me is a group 4b, 5b, or 6b metal as designated in the Periodic Table of Elements; each Q is a hydrocarbyl radical having 1-20 carbon atoms or is a halogen; and $0 \leq p \leq 3$.

A particularly preferred class of isospecific metallocenes are based upon racemic bis(indenyl) ligand structures. The indenyl groups may be substituted or unsubstituted and include aromatic indenyl groups as well as saturated indenyl groups, such as tetrahydroindenyl groups also substituted or unsubstituted. Specific examples of isospecific metallocenes suitable for use in the present invention include racemic-dimethylsilyl bis(2-methyl-4-phenylindenyl) zirconium dichloride, racemic-dimethylsilyl bis(2-methyl-indenyl) zirconium dichloride, racemic-dimethylsilyl bis(2-methyl-4,5-benzoindenyl)zirconium dichloride, racemic-isopropylidene bis(2,3 10 dimethylcyclopentadienyl) zirconium dimethyl, racemic isopropylidene bis(2, 4 dimethylcyclopentadienyl) zirconium dimethyl, ethylene bis(indenyl)zirconium dimethyl, and the corresponding dichlorides. Other metallocenes include ethylene bis(2-methyl indenyl) zirconium dichloride, diphenyl silyl bis(2-methyl indenyl) zirconium dichloride, diphenyl silyl bis(2-methyl, 4-phenyl-indenyl) zirconium dichloride, and diethyl silyl bis(2-methyl, 4-phenyl indenyl) zirconium 15 dichloride.

Bridged syndiospecific metallocenes can be characterized by metallocenes which exhibit bilateral symmetry and are defined by the formula:

wherein Cp_a is a substituted cyclopentadienyl ring, Cp_b is an unsubstituted or substituted cyclopentadienyl ring; each R is the same or different and is a hydrocarbyl radical having 1-20 carbon atoms; each R'_m is the same or different and is a hydrocarbyl radical having 1-20 carbon

5 atoms; R'' is a structural bridge between the cyclopentadienyl groups imparting stereorrigidity to the catalyst and is selected from the group consisting of a substituted or unsubstituted alkylene radical having 1-4 carbon atoms, a silicon hydrocarbyl radical, a germanium hydrocarbyl radical, a phosphorus hydrocarbyl radical, a nitrogen hydrocarbyl radical, a boron hydrocarbyl radical, and an aluminum hydrocarbyl radical; Me is a group 4b, 5b, or 6b metal from the Periodic Table of
10 Elements; each Q is a hydrocarbyl radical having 1-20 carbon atoms or is a halogen; $0 \leq p \leq 3$; $0 \leq m \leq 4$; $1 \leq n \leq 4$; and wherein R'_m is selected such that $(Cp_bR'_m)$ is a different ring than (Cp_aR_n) .
Bridged syndiospecific metallocenes which may be employed in the present invention include
15 diphenylsilylene (cyclopentadienyl)(fluorenyl) zirconium dichloride, a mixture of diphenylsilylene (cyclopentadienyl)(fluorenyl) zirconium dichloride, and isopropylidene (cyclopentadienyl)(2,7-di-
tert-butylfluorenyl) zirconium dichloride, isobutylidene(cyclopentadienyl-1-fluorenyl) zirconium
dimethyl, isopentylidene (cyclopentadienyl-1-fluorenyl) zirconium dimethyl, isopropylidene
20 (cyclopentadienyl-1-fluorenyl) zirconium dimethyl, diphenyl methylene (cyclopentadienyl-1-
fluorenyl) zirconium dimethyl, and the corresponding dichlorides or methylchlorides.

As noted previously by reference to U.S. Patent No. 5,807,800, the bilateral symmetry of a
25 bridged metallocene ligand structure is indicated by the balanced orientation about the broken line
representing a plane of symmetry extending generally through the bridge structure and the transition
metal atom. The concept of bilateral symmetry is useful to illustrate metallocene structures that are

useful for the invention. Other metallocene compounds which lack bilateral symmetry can also be used however as long as the steric environment about the metal is such that the two coordination sites on the transition metal possess opposite enantioface selectivity. To illustrate this point, consider the MePhC - cyclopentadienyl fluorenyl zirconium dichloride. This metallocene lacks 5 bilateral symmetry by virtue of the asymmetric bridge and yet would be suitable for use in the invention. Similarly, $\text{Me}_2\text{C}(2\text{-Me-Cp})(\text{Flu})\text{ZrCl}_2$ would also yield a syndiospecific catalyst although it lacks bilateral symmetry. The key requirement of a transition metal catalyst precursor is that the reaction sites possess opposite enantioface selectivity towards olefin insertion. Visually this can be depicted below. Opposite enantioface selectivity of the metallocene catalyst precursor is 10 established by an arrangement about the metal in which R_2 and R_3 are sterically larger than groups R_6 and R_7 or conversely, R_6 and R_7 are sterically larger than R_2 and R_3 . In the case of 15 $\text{Me}_2\text{CpFluZrCl}_2$, R_2 and R_3 are hydrogen atoms and R_6 and R_7 are hydrocarbyl radicals which are clearly larger than hydrogen.

Condition for Syndiospecific Polymerizations:

R_2 and R_3 are sterically larger than R_6 and R_7

OR

R_6 and R_7 are sterically larger than R_2 and R_3

Condition for Isospecific Polymerizations:

R_2 is sterically larger than R_6

and R_7 is sterically larger than R_3

OR

R_6 is sterically larger than R_2 and

R_3 is sterically larger than R_7

15 Usually, in the metallocenes employed in the present invention, Me is titanium, zirconium, hafnium, or vanadium; Q is, preferably, a methyl or halogen, more preferably chlorine; and k

normally is 2 but may vary with the valence of the metal atom. Exemplary hydrocarbyl radicals include methyl, ethyl, propyl, isopropyl, butyl, isobutyl, amyl, isoamyl, hexyl, heptyl, octyl, nonyl, decyl, cetyl, phenyl, and the like. Other hydrocarbyl radicals include other alkyl, aryl, alkenyl, alkylaryl, or arylalkyl radicals. For metallocenes in which the oxidation state is not stable during use or storage (for example, Group 5-based metallocenes) it is often useful to use halogenated substances such as carbon tetrachloride, chloroform, etc. in order to maintain good catalytic performance.

While different loading factors are preferred for syndiospecific and isospecific catalysts, the same general procedure in loading first the alumoxane and then the metallocene on the support material is applicable for both isospecific and syndiospecific metallocenes as well as for other metallocenes. The invention can be generally described, without regard to the particular metallocene, as follows for a silica support. The silica is dried to remove a substantial amount of its water content. The drying procedure can be carried under nitrogen or vacuum overnight (about 12 hours) at a temperature of about 100°-160°C. The silica should be dried to the point where the amount of weight loss on ignition (LOI) at 300°C is less than 4% , preferably less than 2% and most preferably within the range of about 0.1-1.5 wt.%. The dried silica is then slurried in toluene or another similar aromatic hydrocarbon solvent. A solution of an alumoxane, preferably methylalumoxane (MAO) although other alumoxanes can be used, in toluene (or other aromatic solvent) is then added to the silica/toluene mixture, and as the silica and MAO are mixed together, the resulting slurry is heated to a temperature of about 100°C or more and then heated for a period of several hours. By way of example, where toluene is used as the aromatic solvent, the MAO silica/toluene mixture can be heated at the reflux temperature of the toluene, about 115°C, for a

period of about 4 hours. The resulting product in which the MAO is fixed on the support is then cooled to ambient temperature, about 25°C, over a period of several hours and then allowed to settle so that the particulate silica with the MAO supported thereon settles out of solution without mixing or other agitation. The liquid is removed by decantation, and the particulate material is filtered out 5 and subjected to several toluene washes in order to remove excess alumoxane or other aluminum compounds not fixed on the support. Typically, 2 to 4 toluene washes at ambient temperature conditions will be employed in this phase of the procedure.

At this point the alumoxane-containing support is mixed with chilled toluene of about 10°C or less. Typically, the temperature at this phase and in the subsequent phases will be within the range of 0°-10°C. Substantially cooler temperatures can be used, but are often unnecessary. At this temperature, the metallocene dispersed in the toluene or other aromatic solvent, again at the reduced temperature, is added to the MAO / silica slurry and the resulting mixture agitated for a period of time to allow the metallocene to become reactively supported on the support material with the alumoxane. Although the predominant part of the reaction of the metallocene with the support takes place over an initial period of several minutes, it will usually be desirable to maintain the mixing of the support and metallocene for a period of one or more hours. The mixing time can range up to several hours if desired.

At the conclusion of the support reaction, the solid material is filtered from the liquid and then washed with a cold toluene solution, typically at 0°-10°C, and filtered and washed several 20 times with a paraffinic hydrocarbon solvent such as hexane, again at a temperature of about 10°C or less. Three sequential hexane washes may be carried out in order to substantially reduce the amount of toluene on the support material to a low level typically less than a few percent. At this

stage, cold mineral oil is added to the supported catalyst in the filtrate in order to form a dispersion of the catalyst in the mineral oil. There is, as described above, no necessity of an intervening drying step, so the resulting dispersion of mineral oil will contain a minor amount of the hexane or other paraffinic solvent and even a smaller amount of the toluene or other aromatic solvent. However, a 5 drying step can be applied immediately prior to addition of the mineral oil.

The mineral oil should have a sufficient viscosity to maintain the supported catalyst in a dispersive suspension with mild agitation when it is used in a polymerization reaction. The mineral oil will, of course, have a viscosity substantially greater than the viscosity of the paraffinic hydrocarbon solvent. Typically, at 10°C the paraffinic mineral oil will have a viscosity of about 10 centistokes or more while the viscosity of the paraffinic hydrocarbon solvent again at 10°C will be about two centistokes or less. The final liquid dispersing agent will contain a minor amount of the more volatile paraffinic solvent used in washing toluene off the supported catalyst and an even smaller amount of the aromatic solvent itself. Typically, the minor component, which is indicated above, would be present in about 5-15 wt.% of the mineral oil and will be about .1-13 wt.% of the hexane or other paraffinic solvent or less than 2 wt.% of the toluene or other aromatic solvent.

10 Optionally the oil can be evacuated to remove residual hexane and toluene. As noted previously, the present invention may be employed to incorporate the alumoxane co-catalyst and metallocene on a wide variety of supports. Characteristics of many catalyst supports such as these described above is that the alumoxane is deposited primarily on the surface of the support and the 20 metallocene then applied over the alumoxane to provide a configuration in which the alumoxane forms an intermediate shell encompassing the support particle and the metallocene forms an outer shell overlying the alumoxane. The treatment with the toluene or other aromatic solvent subsequent

to the alumoxane support reaction removes excess alumoxane which is not fixed on the support so that it, together with the associated metallocene later applied, does not become released from the support during the polymerization reaction.

Similar considerations apply with respect to the subsequently-applied metallocene. The 5 metallocene, as noted above, forms in the case of the surface supports such as the silica described below, with the metallocene supported as an outer shell surrounding the organoaluminum co-catalyst. Excess metallocene is subject to becoming dislodged during the polymerization reaction with the attendant production of fouling within the polymerization reactor. By the initial cold temperature washes with the toluene or other aromatic solvents on the freshly supported catalyst, excess metallocene is removed to produce the final product in which substantially all of the metallocene is fixed to the support. In order to avoid any desorption of metallocene by residual toluene, the subsequent cold washes with hexane or other hydrocarbon removes the great preponderance for metallocene desorption.

As noted above, the invention is particularly applicable to silica supports having an average 15 particle size within the range of about 10-100 microns in which the organoaluminum compounds and later the metallocene are supported on the outer surface of the support particles. Such support particles include silica supports of a small particle size which are generally spheroidal in configuration and have an average particle size within the range of 10-15 microns, specifically about 12 microns. Other silica supports in which the alumoxane and metallocene are supported 20 primarily on the surface are silica supports in which the silica particles are irregular or granular in shape can be characterized by a somewhat larger average particle size of about 10-100 microns. In addition to the silica support H-121 identified previously, such silica particles include silicas

available from Fuji Silysa Chemical Company, Ltd., under the designations of G6 having a pore volume of about 0.7 millimeters per gram and Q10, the latter being of a spheroidal configuration as contrasted with G6 which is of an irregular granular configuration.

As described below, the relative amount of alumoxane on the support will, in preferred 5 embodiments, be present in an amount 0.5-1.5 parts by weight alumoxane in the starting reaction mixture to 1 part by weight support material, but the amounts may vary within this range depending upon the particular support and whether an isospecific or syndiospecific metallocene is involved. More specifically, for such metallocenes the weight ratio of alumoxane to the silica support material is within the range of 0.7-1.0. Metallocene loadings will normally vary from about 0.1-6 wt.% of 10 the MAO / support material.

With either syndiospecific or isospecific metallocenes, several substantial improvements are observed to result from the practice of the present invention over the typical prior art procedures described above. The catalyst activity is substantially higher for both isospecific and syndiospecific metallocenes, increasing by as much as twofold over the activity of the catalyst prepared following 15 the prior art practice. The syndiospecific and isospecific catalysts showed increase in activity when the TIBAL aging procedure was followed. The polymer product produced by the catalysts formed in accordance with the present invention has a higher bulk density, typically increased within the range of about 15-20% for the isospecific metallocenes. For instance, for both the isospecific and syndiospecific catalysts, the shelf-life of the catalyst dispersed in the mineral oil without the 20 conventional intervening drying step is much greater than the catalyst produced by conventional techniques. The improved shelf-life may be characterized on the order of 3 months or more versus a matter of weeks of shelf life for catalysts produced by conventional techniques.

Experimental work respecting the present invention was carried out employing bridged isospecific and syndiospecific catalysts. The isospecific catalyst was racemic-dimethylsilyl bis(2-methyl-4-phenylindenyl) zirconium dichloride. To illustrate the invention with a syndiospecific catalyst the following metallocene was used: diphenylsilylene(cyclopentadienyl)(fluorenyl) zirconium dichloride. To further illustrate that the invention is useful in the production of broad molecular weight distribution resins, a catalyst was prepared containing 1.6 wt.% of diphenylmethylsilylene (cyclopentadienyl)(fluorenyl) zirconium dichloride and 0.4 wt.% isopropylidene (cyclopentadienyl)(2,7-di-*tert*-butylfluorenyl) zirconium dichloride. These isospecific and syndiospecific metallocenes were supported on MAO / silica using the process of the present invention and also supported in accordance with the standard technique carried out at room temperature or above and in which the catalyst component was dried in accordance with conventional procedures. In general, the supported isospecific catalyst prepared by the standard technique had activities ranging from about 3,000-6,000 grams of polymer per grams of catalyst per hour (g/g/h) versus activities for the catalyst produced in accordance with the present invention within the range of about 8,000-13,500 g/g/h. Bulk density of the polymer produced from the prior art catalyst ranged from about 0.3-0.36 g/ml whereas the bulk density of the polymer produced from the catalyst of the present invention ranged from about 0.35-0.4 g/ml. In addition, following the present invention the shelf life was increased from about two weeks to twelve weeks or more. Finally, the catalyst produced in accordance with the present invention could be stored as a non-20 pyrophoric slurry, as contrasted with the pyrophoric solid produced by the prior art techniques.

The following examples illustrate the practice of the present invention.

General Procedure for Unaged Syndiotactic Polypropylene (sPP) Polymerization

Polymerizations were performed in a 4L Autoclave Engineers' Zipperclave reactor equipped with a Magnedrive pitched-blade impeller operating at 800 rpm. The reactor is jacketed to maintain polymerization temperature within 1°C of a setpoint of 60°C. The dry and
5 de-oxygenated reactor was charged under ambient conditions (25°C) with 750 g of liquid propylene and 41.2 mmoles of hydrogen. The catalyst/oil slurry (36 mg catalyst contained) was added to a stainless steel cylinder with 109 mg of triisobutylaluminum. The catalyst / cocatalyst were precontacted for approximately 3 minutes and then flushed into the reactor with an additional 750 g aliquot of propylene. The reactor was heated to 60°C over about 3 minutes and then the reaction was allowed to proceed for 60 minutes. The reactor contents were quickly vented and the polymer was allowed to dry overnight in a ventilated enclosure.

General Procedure for Aged sPP Polymerization

The same procedure as described above was used except that the catalyst (144 mg) and TIBAL (144 mg) were precontacted for 12 hours in a 20 mL Wheaton vial. An aliquot of the aged catalyst (36 mg) was combined with an additional 72 mgs of TIBAL and flushed into the reactor with liquid propylene as described above. The precontact time between the catalyst and the additional aliquot of TIBAL was again fixed at approximately 3 minutes.

20 General Procedure for Unaged Isotactic Polypropylene (miPP) Polymerization

Polymerizations were performed in a 4L Autoclave Engineers' Zipperclave reactor equipped with a Magnedrive pitched-blade impeller operating at 800 rpm. The reactor was

jacketed to maintain polymerization temperature within 1°C of a setpoint of 67°C. The dry and de-oxygenated reactor was charged under ambient conditions (25°C) with 750 g of liquid propylene and 10 mmoles of hydrogen. The catalyst/oil slurry (36 mg catalyst contained) was added to a stainless steel cylinder with 72 mg of triethylaluminum. The catalyst / cocatalyst 5 were precontacted for approximately 3 minutes and then flushed into the reactor with an additional 750 g aliquot of propylene. The reactor was heated to 67°C over about 3 minutes and then the reaction was allowed to proceed for 60 minutes. The reactor contents were quickly vented and the polymer was allowed to dry overnight in a ventilated enclosure.

General Procedure for Aged miPP Polymerization

The same procedure as described above for the unaged isotactic polypropylene polymerization was used except that the catalyst (144 mg) and TIBAL (144 mg) were precontacted for 12 hours in a 20 mL Wheaton vial. An aliquot of the aged catalyst (36 mg) was combined with an additional 36 mgs of TEAL and flushed into the reactor with liquid propylene 15 as described above. The precontact time between the catalyst and the additional aliquot of TEAL was again fixed at approximately 3 minutes. The rest of the procedure is the same as above.

Bulk Density Measurement

Bulk density measurements were conducted by weighing the unpacked contents of a 100 20 mL graduated cylinder containing the polymer powder.

Melt Flow Index Measurement

Polymer melt flow was recorded on a Tinius-Olsen Extrusion Plastometer at 230°C with a 2.16 Kg mass. Polymer powder was stabilized with approximately 1 mg of 2,6-ditert-butyl-4-methylphenol (BHT).

5

Preparation of Methylaluminoxane-supported Silica

Silica gel (160g, Asahi Glass Sunsphere H-121C) was dried in an oven at 150°C for 62 hours. The weight loss on heating of the dried silica was recorded using a Thermogravimetric Analyzer. The weight loss at 150, 300 and 900°C were found to be 0.97%, 1.13% and 5.49% respectively.

20g of dried silica was placed in a 1 liter, 3-necked round-bottomed flask in a glove box with a condenser attached. To this was added 200 mL of dry deoxygenated toluene. The slurry was briefly agitated and 64 milliliters of 30 wt% MAO in toluene was added. The flask was sealed and removed from the glove box and attached to a Schlenk manifold under a slight positive pressure of nitrogen. The reaction mixture was heated to 115°C and allowed to reflux for 4 hours using a magnetic stirrer. The slurry was allowed to cool to room temperature and settle. The toluene supernatent was removed via cannulae and the wet product was washed sequentially with two 200 mL portions of toluene followed by three 200 mL portions of dry, deoxygenated hexane. The MAO on silica was then dried in vacuo to obtain the white solid. Drying of the MAO on silica in this instance provides convenience in the laboratory evaluation of different catalysts.

Comparative Example 1. Preparation of sPP Catalyst

3 g of MAO on H121C silica was added to a 100 mL round-bottomed flask with 30 mLs of toluene and the flask was cooled to 0°C. Diphenylsilylene(cyclopentadienyl)(fluorenyl)-zirconium dichloride (45 mg) was slurried into 10 mLs of toluene in a 20 mL Wheaton vial. The metallocene slurry was added to a stirred solution of the MAO on silica. The transfer of metallocene was completed with a second 10 mL portion of toluene. The metallocene and MAO/silica was allowed to react for a period of 1.5 hours at 0°C. The solids were allowed to settle and the supernatent was removed via cannulae. The wet supported catalyst was washed with one 50 mL portion of toluene and again the solids were allowed to settle and the supernatent was removed via cannulae. The wet supported catalyst was then washed sequentially with 3, 50 mL portions of hexane. Following the third decantation of the hexane, the catalyst slurry was dried under vacuum. 2.6 g of dry supported sPP catalyst was isolated.

Comparative Example 2. Preparation of sPP Catalyst

5 g of MAO on H121C silica was added to a 100 mL round-bottomed flask with 30 mLs of toluene and the flask was cooled to 0°C. Diphenylsilylene(cyclopentadienyl)(fluorenyl)-zirconium dichloride (80 mg) and isopropylidene(cyclopentadienyl)(2,7-bis^{tert}-butylfluorenyl)-zirconium dichloride (20 mg) was slurried into 10 mLs of toluene in a 20 mL Wheaton vial. The metallocene slurry was added to a stirred solution of the MAO on silica. The transfer of metallocene was completed with a second 10 mL portion of toluene. The metallocene and MAO/silica was allowed to react for a period of 1.5 hours at 0°C. The solids were allowed to

settle and the supernatent was removed via cannulae. The wet supported catalyst was washed with one 50 mL portion of toluene and again the solids were allowed to settle and the supernatent was removed via cannulae. The wet supported catalyst was then washed sequentially with 3, 50 mL portions of hexane. Following the third decantation of the hexane, the catalyst slurry was 5 dried under vacuum. 4.6 g of dry supported sPP catalyst was isolated.

Example 1: Preparation of sPP Catalyst

5 g of MAO on H121C silica was added to a 100 mL round-bottomed flask with 30 mLs of toluene and the flask was cooled to 0°C. Diphenylsilylene(cyclopentadienyl)(fluorenyl) zirconium dichloride (80 mg) and isopropylidene(cyclopentadienyl)(2,7-bis^{tert}-butylfluorenyl) zirconium dichloride (20 mg) was slurried into 10 mLs of toluene in a 20 mL Wheaton vial. The metallocene slurry was added to a stirred solution of the MAO on silica. The transfer of metallocene was completed with a second 10 mL portion of toluene. The metallocene and MAO/silica was allowed to react for a period of 2 hours at 0°C. The solids were allowed to settle and the supernatent was removed via cannulae. The wet supported catalyst was washed at 0°C with one 50 mL portion of toluene and again the solids were allowed to settle and the supernatent was removed via cannulae. The wet supported catalyst was then washed sequentially with 3, 50 mL portions of hexane at 0°C. Following the third decantation of the hexane, the wet catalyst slurry was diluted with 45 g of mineral oil. The sPP supported catalyst was isolated as a 7.2 % 20 solids slurry.

Example 2: Preparation of sPP Catalyst

5 g of MAO on H121C silica was added to a 100 mL round-bottomed flask with 30 mLs of toluene and the flask was cooled to 0°C. Diphenylsilylene(cyclopentadienyl)(fluorenyl) zirconium dichloride (100 mg) was slurried into 10 mLs of toluene in a 20 mL Wheaton vial.

5 The metallocene slurry was added to a stirred solution of the MAO on silica. The transfer of metallocene was completed with a second 10 mL portion of toluene. The metallocene and MAO/silica was allowed to react for a period of 1.5 hours at 0°C. The solids were allowed to settle and the supernatent was removed via cannulae. The wet supported catalyst was washed at 0°C with one 50 mL portion of toluene and again the solids were allowed to settle and the supernatent was removed via cannulae. The wet supported catalyst was then washed sequentially at 0°C with 3, 50 mL portions of hexane. Following the third decantation of the hexane, the catalyst slurry was dried briefly under vacuum and then slurried into mineral oil (45 g) to make a 9.0 % solids slurry.

Comparative Example 3: Preparation of miPP Catalyst

5 g of MAO on H121C silica was added to a 100 mL round-bottomed flask with 25 mLs of toluene at ambient temperature. Racemic dimethylsilylene bis(2-methyl-4-phenyl-indenyl) zirconium dichloride (92 mg) was slurried into 15 mLs of toluene in a 20 mL Wheaton vial. The metallocene slurry was added to a stirred solution of the MAO on silica. The metallocene and 20 MAO/silica was allowed to react for a period of 1 hour at room temperature. The solids were allowed to settle and the supernatent was removed via cannulae. The wet supported catalyst was washed sequentially with 3, 50 mL portions of hexane. Following the third decantation of the

hexane, the catalyst slurry was dried under vacuum. 5 g of dry supported miPP catalyst was isolated.

Example 3: Preparation of miPP Catalyst

5 5 g of MAO on H121C silica was added to a 100 mL round-bottomed flask with 25 mLs of toluene at ambient temperature. Racemic dimethylsilylene bis(2-methyl-4-phenyl-indenyl) zirconium dichloride (92 mg) was slurried into 15 mLs of toluene in a 20 mL Wheaton vial. The metallocene slurry was added to a stirred solution of the MAO on silica at 0°C. The metallocene and MAO/silica were allowed to react for a period of 2 hours at 0°C. The solids were allowed to settle and the supernatent was removed via cannulae. The wet supported catalyst was washed sequentially with 3, 50 mL portions of hexane at 0°C. Following the third decantation of the hexane, 48 g of mineral oil was added to the wet catalyst slurry to give a final solids content of 7.3%.

Example 4: Preparation of miPP Catalyst

10 10 g of MAO on H121C silica was added to a 250 mL round-bottomed flask with 75 mLs of toluene at ambient temperature. Racemic dimethylsilylene bis(2-methyl-4-phenyl-indenyl) zirconium dichloride (184 mg) was slurried into 25 mLs of toluene in a 60 mL Wheaton vial. The metallocene slurry was added to a stirred solution of the MAO on silica at 0°C. The metallocene and MAO/silica were allowed to react for a period of 1 hours at 0 °C. The solids were allowed to settle and the supernatent was removed via cannulae. The wet supported catalyst was washed sequentially with 3, 100 mL portions of hexane. Following the third

decantation of the hexane, 100 g of mineral oil was added to the wet catalyst slurry. The oil-slurried catalyst was evacuated for 45 minutes to remove most of the volatile components to give a final solids content of 7.3%. This example demonstrates that an optional evacuation step can be utilized in the described procedure.

5 Polymerization results are summarized in Table 1. In Table 1 the first column designates the catalyst used in the polymerization by reference to the above comparative example or examples with comparative example identified by the designation "CE" (thus, CE-1 for Comparative Example 1) and the examples identified by the designation "E" (thus, E-1) for Example 1. The second column indicates whether or not the above-described aging procedure in TIBAL was employed. The third column indicates the activity of the catalyst in grams of propylene per gram of catalyst per hour, and the fourth column indicates the bulk density in grams per cubic centimeter of the polymer product. The fifth column indicates the melt flow rate, and the sixth column indicates the xylene solubles content (XS) of the polymer product. Column 7 indicates the melting temperature of the polymer product. The eighth column indicates the molecular weight is thousandths, and the last column, the molecular weight distribution (D) as indicated by M_w/M_n , with M_w indicating the weight average molecular weight and M_n , the number average molecular weight. The inventive procedure described herein results in a substantial increase in catalyst activity (see Example 1 and Comparative Example 1 for instance). The improvement was also apparent when the catalysts were aged with an aluminum
10 alkyl for an extended period of time.

Example 2	No	13,000	0.40	8.4	4.2	130.5	118	4.0
CE Example 3	No	6,500	0.36	4.0	-	-	-	-
Example 3	No	10,000	0.37	3.1	-	-	-	-
Example 4	No	10,600	0.38	3.8	-	-	-	-
CE Example 1	Yes	14,900	0.37	1.5	1.6	127.3	174	2.6
Example 1	Yes	24,000	0.35	1.2	-	-	-	-
CE Example 2	Yes	15,600	0.35	7.0	3.8	129.3	127	4.1
Example 2	Yes	25,000	0.41	7.3	5.2	130.5	119	4.4
Example 4	Yes	11,100	0.40	0.61	-	-	-	-

Examples 1 and 2 and comparative examples 1 and 2 were tested under standard sPP polymerization conditions. Examples 3 and 4 and comparative examples 3 and 4 were tested under standard miPP polymerization conditions.

Having described specific embodiments of the present invention, it will be understood that modifications thereof may be suggested to those skilled in the art, and it is intended to cover all such 10 modifications as fall within the scope of the appended claims.
